Discussion: TopoLayout

TopoLayout: Multi-Level Graph Layout by Topological Features

Daniel Archambault, Tamara Munzner *IEEE Member*, David Auber

Abstract—We describe TopoLayout, a feature-based, multi-level algorithm that draws undirected graphs based on the topological features they contain. Topological features are detected recursively inside the graph, and their subgraphs are collapsed into single nodes, forming a graph hierarchy. Each feature is drawn with an algorithm tuned for its topology. As would be expected from a feature-based approach, the runtime and visual quality of TopoLayout depends on the number and types of topological features present in the graph. We show experimental results comparing speed and visual quality for TopoLayout against four other multi-level algorithms on a variety of datasets with a range of connectivities and sizes. TopoLayout frequently improves the results in terms of speed and visual quality on these datasets.

Index Terms—Information Visualization, Graphs and Networks, Graph Visualization

I. INTRODUCTION

Recently, **multi-level** approaches for graph drawing have been studied to overcome the size and visual quality limitations of previous work. Multi-level algorithms typically construct a graph hierarchy with the original graph at the leaf level and coarser approximations at higher levels. Current multi-level approaches typically only exploit local connectivity in the graph and treat all nodes and edges similarly. The resulting drawings are uniform, but low-level structure within the high-level structure of the graph is difficult to see.

We introduce a **feature-based** approach to multi-level graph drawing. In this approach, features of interest are recursively detected in the graph and replaced with meta-nodes at a coarser level. Appropriate drawing algorithms for each feature are selected based on the type of feature detected. Our approach to feature-based, multi-level graph drawing recursively detects **topological features** such as trees, connected components, and biconnected components, which have been well studied in the literature. We also detect highly connected clusters: features of interest in power law or small world graphs. To show

that we can expand our system beyond strict topological features, we detect when the high-dimensional embedder (HDE) [22] algorithm is a suitable choice for layout. HDE is an efficient algorithm for drawing a specific subset of general graphs, many of which are grids.

The primary contribution of this work is TopoLayout, the first feature-based, multi-level algorithm. Unlike previous multi-level algorithms, the graph hierarchy is drawn bottom-up, taking the space required to draw the features into account at higher levels of the graph hierarchy. Thus, all of our layout algorithms should be **area-aware**; that is, take varying node size into account. TopoLayout also introduces passes to eliminate all node-node overlaps and to reduce the number of node-edge and edge-edge crossings.

The performance of TopoLayout is compared to existing multi-level algorithms. Although TopoLayout does have its limitations, the approach is often faster and better able to illustrate low-level structure in the context of high-level graph structure.

II. PREVIOUS AND RELATED WORK

Given a general, undirected graph G consisting of N nodes and E edges, we concern ourselves with the problem of drawing G in two dimensions. Nodes are assigned two dimensional coordinates, and if two nodes share an edge it is drawn between them as a straight line.

The problem of drawing general, undirected graphs has been well studied. Before the late 1990s, the methods were primarily focused on force-directed approaches [7], [10]–[12], [20]. These methods perform well for many types of graphs, but do not scale to graphs of thousands of nodes. To overcome this limitation, multi-level approaches and approaches which rely more heavily on user interaction have been proposed. In addition, a few previous approaches do exploit topology. We also describe the HDE approach, so that our HDE detector can be understood.

In addition to the work presented here, we have also described some preliminary work on TopoLayout in a poster [2].

Abstract. Algorithms for laying out large graphs have seen significant progress in the past decade. However, browsing large graphs remains a challenge. Rendering thousands of graphical elements at once often results in a cluttered image, and navigating these elements naively can cause disorientation. To address this challenge we propose a method called GraphMaps, mimicking the browsing experience of online geographic maps.

GraphMaps creates a sequence of layers, where each layer refines the previous one. During graph browsing, GraphMaps chooses the layer corresponding to the zoom level, and renders only those entities of the layer that intersect the current viewport. The result is that, regardless of the graph size, the number of entities rendered at each view does not exceed a predefined threshold, yet all graph elements can be explored by the standard zoom and pan operations.

GraphMaps preprocesses a graph in such a way that during browsing, the geometry of the entities is stable, and the viewer is responsive. Our case studies indicate that GraphMaps is useful in gaining an overview of a large graph, and also in exploring a graph on a finer level of detail.

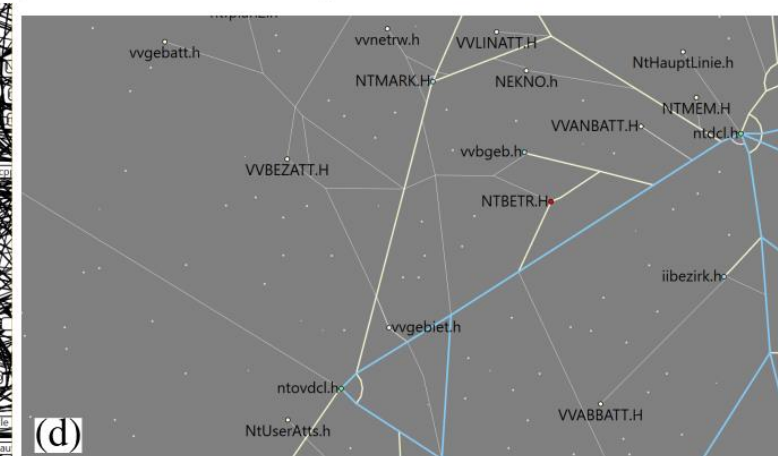

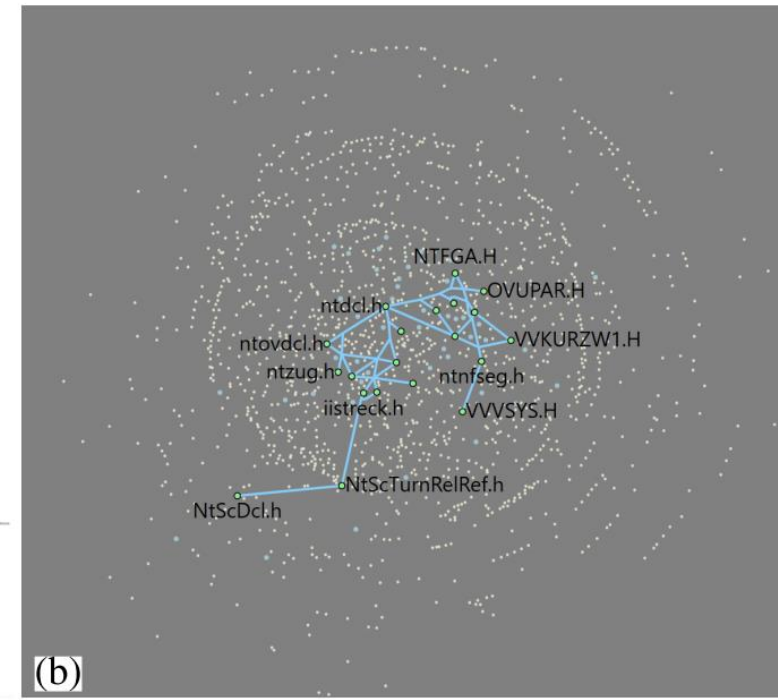

1 Introduction

Graphs are ubiquitous in many different domains such as information technology, social analysis or biology. Graphs are routinely visualized, but their large size is often a barrier. The difficulty comes not from the layout which can be calculated very fast. (For example, by using Brandes and Pich's algorithm [2] a graph with several thousand nodes and links can be laid out in a few seconds on a regular personal computer.) Rather, viewing and browsing these large graphs is problematic. Firstly, rendering thousands of graphical elements on a computer might take a considerable time and may result in a cluttered image if the graph is dense. Secondly, navigating thousands of elements rendered naively disorients the user.

Our intention is to provide a graph browsing experience similar to that of online geographic maps, for example, Bing or Google Maps. We propose a set of requirements for such a visualization and introduce a method, GraphMaps, fulfilling these requirements. GraphMaps renders a graph as an interactive map by displaying only the most

Design goals:

- Reveal most details using only zoom in, zoom out, and pan operations.
 - Assign view levels with node/edge importance
 - Interactions e.g. node/edge highlighting or search
- Mental map preservation
 - Node positions and edge trajectories should not change
- Limit visual clutter
 - Hard bound on number of rendered elements

Latest published: 30 Jul 2014, 3:177 (doi: [10.12688/f1000research.4784.1](https://doi.org/10.12688/f1000research.4784.1))

Abstract

Dendrograms are graphical representations of binary tree structures resulting from agglomerative hierarchical clustering. In Life Science, a cluster heat map is a widely accepted visualization technique that utilizes the leaf order of a dendrogram to reorder the rows and columns of the data table. The derived linear order is more meaningful than a random order, because it groups similar items together. However, two consecutive items can be quite dissimilar despite proximity in the order. In addition, there are 2^{n-1} possible orderings given n input elements as the orientation of clusters at each merge can be flipped without affecting the hierarchical structure. We present two modular leaf ordering methods to encode both the monotonic order in which clusters are merged and the nested cluster relationships more faithfully in the resulting dendrogram structure. We compare dendrogram and cluster heat map visualizations created using our heuristics to the default heuristic in R and seriation-based leaf ordering methods. We find that our methods lead to a dendrogram structure with global patterns that are easier to interpret, more legible given a limited display space, and more insightful for some cases. The implementation of methods is available as an R package, named "dendsort", from the CRAN package repository. Further examples, documentations, and the source code are available at [<https://bitbucket.org/biovizleuven/dendsort/>].

GIB Croissant-Doughnut: The Croissant

$$\text{Group Area} = a * \text{width} * \text{height} * n / N$$

GIB Croissant-Doughnut: Choosing Between

Definitions:

- **G**: Number of groups in network
- **G-degree**: For a group, the number of connected groups
- **G-skewness**: Fraction of nodes that are members of two most connected groups (highest G-degree).

Empirically determined values:

- **Case1: $G \leq 3$ or $G\text{-skewness} < 0.1$** : Layout the group boxes using the ST-GIB layout
- **Case2: $G > 3$ and $0.1 \leq G\text{-skewness} \leq 0.45$** : Layout the group boxes using Doughnut layout
- **Case3: $G > 3$ and $G\text{-skewness} > 0.45$** : Layout the group boxes using Croissant layout.

GiB Force-Directed: Algorithm

Putting It All Together

Layout depends on task requirements: space-filling vs. showing relationships

- Treemap
- Croissant-Doughnut
- Force-directed

Automatic choices:

- Croissant-Doughnut
 - Croissant for more evenly distributed groups
 - Doughnut for a few large groups
- Disconnected components*
 - Treemap outer layout
 - Nested GIB layouts
- Rotate/flip to reduce edge crossings*

Empirical Evaluation
